1. A 6.0 kg block is held at rest on a horizontal, frictionless air table. Two forces are pulling on this block in the directions shown in the diagram below.

Table Viewed from Above

What will be the magnitude of the acceleration on the 6.0 kg block at the moment it is released?

## Components:

## Answer:

$$
\left.\begin{array}{rl}
\mathrm{a} & =\frac{F_{\text {net }}}{m} \\
& =\frac{43.4 \mathrm{~N}}{6.0 \mathrm{~kg}} \\
& =7.2 \mathrm{~m} / \mathrm{s}^{2}

2. A 4000 kg space vehicle consists of a 2500 kg main capsule and a 1500 kg probe. The space vehicle is travelling at $120 \mathrm{~m} / \mathrm{s}$ when an explosion occurs between the capsule and the probe. As a result, the probe moves forward at $140 \mathrm{~m} / \mathrm{s}$, as shown in the diagram below.

a) (i) What is the speed of the main capsule after the explosion?
(3 marks)

$$
\begin{aligned}
& \left.\begin{array}{l}
\mathrm{m}_{1} \mathrm{v}_{1}+\mathrm{m}_{2} \mathrm{v}_{2}=\mathrm{m}_{1} \mathrm{v}_{1}^{\prime}+\mathrm{m}_{2} \mathrm{v}_{2}^{\prime} \\
\left(\mathrm{m}_{1}+\mathrm{m}_{2}\right) \mathrm{v}=\mathrm{m}_{1} \mathrm{v}_{1}^{\prime}+\mathrm{m}_{2} \mathrm{v}_{2}^{\prime}
\end{array}\right\} \leftarrow \mathbf{1} \text { mark } \\
& \left.\begin{array}{l}

\end{array}\right\} \quad \leftarrow \mathbf{1} \text { mark }
$$

b) Define impulse and briefly explain why the impulse on the probe is equal in magnitude to the impulse on the main capsule.

Impulse is a force acting for a given time interval, or a change in momentum. ( $\mathbf{1}$ mark)
(i) Newton's Third Law states that for every force there is an equal and opposite reacting force. As the time of the explosion is equal for both the probe and the capsule, the impulse ( $\mathrm{F} \Delta \mathrm{t}$ ) must be equal and opposite also.

OR

(ii) Impulse is equal to a change in momentum. As momentum is conserved, the momentum gained by the probe must equal the momentum lost by the capsule

7. In a cathode-ray tube, electrons are accelerated from the cathode towards the anode by an accelerating voltage $\mathrm{V}_{\mathrm{a}}$. After passing through the anode, the electrons are deflected by the two oppositelycharged parallel plates.

If the accelerating voltage $\mathrm{V}_{\mathrm{a}}$ is increased, will the deflection increase, decrease, or remain the same? Using principles of physics, explain your answer.
(4 marks)

The deflection y will decrease.
If $\mathrm{V}_{\mathrm{a}}$ is increased, the electrons are given a greater kinetic energy: e.g., $\mathrm{V}_{\mathrm{a}}=\frac{\Delta \mathrm{E}_{\mathrm{k}}}{\mathrm{q}}$. Hence, the electrons are moving faster, so they spend less time between the plates. A force accelerates the electrons transversely between the plates; however, as the acceleration occurs for a shorter time, their deflection is reduced; e.g., $y=\frac{1}{2} a t^{2}$.
