

## 6.1 Developments of the Periodic Table

### Who developed the Periodic Table and how did they do it?

- Dimitri Mendeleev, a Russian scientist, is the father of the Periodic Table
- Mendeleev's work occurred the same time another scientist, a German physicist named Julius Lothar Mayer, was working on creating a Periodic Table as well
- the two worked independently but produced similar tables in 1869
- he grouped known elements together based on similar properties
- this left some gaps in the table that Mendeleev first produced
- below is a portion of Mendeleev's first Periodic Table

<b>Reihen</b>	<b>Gruppe I</b> — <b>R<sup>2</sup>O</b>	<b>Gruppe II</b> — <b>RO</b>	<b>Gruppe III</b> — <b>R<sup>2</sup>O<sup>3</sup></b>	<b>Gruppe IV</b> <b>RH<sup>4</sup></b> <b>RO<sup>2</sup></b>
<b>1</b>	<b>H = 1</b>			
<b>2</b>	<b>Li = 7</b>	<b>Be = 9,4</b>	<b>B = 11</b>	<b>C = 12</b>
<b>3</b>	<b>Na = 23</b>	<b>Mg = 24</b>	<b>Al = 27,3</b>	<b>Si = 28</b>
<b>4</b>	<b>K = 39</b>	<b>Ca = 40</b>	<b>-- = 44</b>	<b>Ti = 48</b>
<b>5</b>	<b>(Cu = 63)</b>	<b>Zn = 65</b>	<b>-- = 68</b>	<b>-- = 72</b>
<b>6</b>	<b>Rb = 85</b>	<b>Sr = 87</b>	<b>?Yt = 88</b>	<b>Zr = 90</b>
<b>7</b>	<b>(Ag = 108)</b>	<b>Cd = 112</b>	<b>In = 113</b>	<b>Sn = 118</b>

- Mendeleev based this table on the atomic weights of the elements and found that some elements had similar properties that occur periodically → hence the name Periodic Table
- the table led to Mendeleev's Periodic Law, which states:  
*The properties of the elements recur periodically when the elements are arranged in increasing order by their atomic weight.*
- the modern Periodic Law states the same thing only the elements are arranged by *atomic number*
- in the modern Periodic Table, the elements within a group or *family* share properties that allow us to predict the behaviour of elements in that group

Group #	Group Name	Properties
1	Alkali Metals	<ul style="list-style-type: none"><li>➤ form hydroxides → very basic</li><li>➤ high metallic behaviour</li><li>➤ good reducing agents</li><li>➤ high electrical and heat conductivity</li><li>➤ contain one outer shell electron</li><li>➤ forms ions with a charge of +1</li></ul>
2	Alkaline Earth Metals	<ul style="list-style-type: none"><li>➤ good metallic properties including conductivity and reduction ability → not as good as alkali metals (some have low solubility in water)</li><li>➤ contain two outer shell electrons</li><li>➤ forms ions with a charge of +2</li></ul>
17	Halogens	<ul style="list-style-type: none"><li>➤ reactive, nonmetals</li><li>➤ relatively high electronegativities</li><li>➤ are short 1 electron for a full outer shell</li><li>➤ forms ions with a charge of -1</li></ul>

		<ul style="list-style-type: none"><li>➤ can form gases or liquids</li><li>➤ at room temp: F, Cl gases, Br liquid, &amp; I, As solids</li><li>➤ 7 valence e<sup>-</sup> (3s<sup>2</sup> 3p<sup>5</sup>)</li></ul>
Group #	Group Name	Properties
18	Noble Gases	<ul style="list-style-type: none"><li>➤ the least reactive of all families → inert</li><li>➤ are all gases at STP</li><li>➤ inertness due to a full outer shell</li><li>➤ low reactivity does not mean lack of reactivity</li></ul>

- Transitional elements: all metals and most are hard solids with high melting & boiling pts.
- Chemical behavior complex due to similarities within a period and a group
- Some have distinct colour due to addition of last electrons in inner d orbital. Electrons in d orbitals closer to nucleus.
